This is the third and final article in a series about interprocess communication (IPC) in Linux. The first article focused on IPC through shared storage (files and memory segments), and the second article does the same for basic channels: pipes (named and unnamed) and message queues. This article moves from IPC at the high end (sockets) to IPC at the low end (signals).

int bind (int sockfd, const struct sockaddr *addr, socklen_t addrlen); After creation of the socket, bind function binds the socket to the address and port number specified in addr (custom data structure). In the example code, we bind the server to the localhost, hence we use INADDR_ANY to specify the IP address.
